Certified Behavioral Analysis (ZVA+)

The Inversion of Recruiting: Efficiency Over Chance

An Initial Overview

The Problem

Companies worldwide invest enormous resources to find suitable employees. Yet every hire remains an experiment — until practice reveals whether the new employee truly fits the role and the team.

Even the most modern recruiting tools only evaluate résumés or body language — not a person's mental style, cognitive consistency, or resilience.

The result: mismatches, high turnover, and productivity losses.

Traditional recruiting is an inefficient, costly trial-and-error system.

The Solution

ZVA+ reverses this process:

- Instead of companies screening applicants, applicants have themselves pre-emptively certified — through an AI-based behavioral analysis that objectively and impartially measures how a person thinks, reacts, and solves problems.
- The analysis is based on a multi-hour interaction with a specialized Large Language Model (LLM). From this unstructured dialogue, the system derives precise cognitive markers — such as systematic thinking, stress resistance, conflict behavior, or autonomy preference.
- The result is a standardized, AI-validated personality profile that enables companies to make well-founded, fact-based hiring decisions.

The Business Model

1. Applicants pay for their ZVA+ certification in order to significantly increase their market prospects.
2. Companies pay license fees for access to a pre-screened, high-quality candidate pool.

This creates an inverted cash flow with dual benefit:

Applicants gain credibility.

Employers save costs and avoid poor hiring decisions.

Target Audience and Market Segment

ZVA+ is aimed at companies where mental precision, resilience, and cognitive efficiency determine economic success.

The focus is on knowledge-intensive industries such as technology, consulting, finance, research, and engineering — organizations where people must understand, structure, and manage complex systems.

These include start-ups and scale-ups in the tech sector, strategy and management consultancies, investment and financial firms, DeepTech and life science companies, as well as analytically-oriented leadership roles in large corporations.

ZVA+ delivers an immediate productivity and quality advantage here, since mismatches in such positions incur disproportionately high costs.

As digitalization and automation advance, this target group grows exponentially:

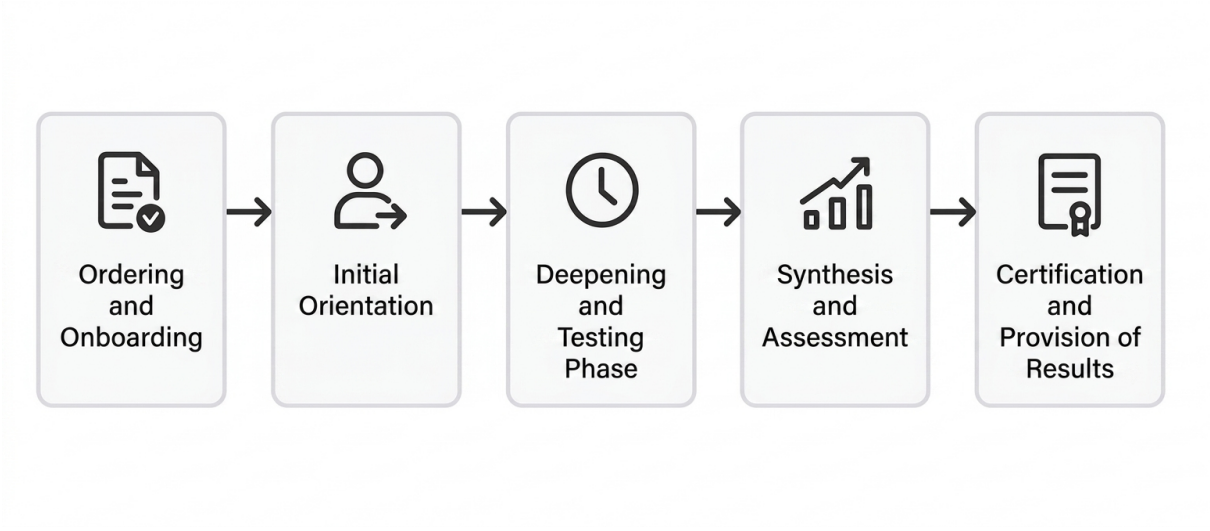
- The more routine tasks are displaced by technology, the more valuable measurable human cognitive performance becomes — and with it, the necessity to assess it precisely.
- ZVA+ is therefore not limited to a niche, but addresses the entire global knowledge and decision-making labor market of the future.

The Investment Lever

With capital for technological scaling, regulatory compliance, and international validation, ZVA+ becomes the global benchmark for objective personnel analysis.

The goal: the elimination of chance in recruiting — through measurable, certified suitability.

The ZVA+ Analysis Process



1. Commissioning and Onboarding

- The candidate registers on the ZVA+ platform, selects the desired certification level (e.g., Standard or Executive), and completes a brief onboarding.
- During this step, the target role, language level, and consent to data use are established.
- The AI instance is then personalized and initialized — at this point it only knows the analysis parameters, not the candidate's identity.

2. Initial Orientation

The LLM begins with an adaptive exploration phase:

- It poses open-ended yet purposefully structured questions to capture the user's thinking style, prioritization, and communication logic.
- The dialogue resembles a coaching conversation but is entirely data-driven.
- The system collects qualitative text data (responses, word choice, reaction patterns) and derives initial hypotheses about the cognitive structure from them.

3. Deepening and Stress Phase

In this phase, the AI actively tests the stability of the thinking style:

- It confronts the user with contradictions, time-pressure or dilemma scenarios, and observes whether the argumentation logic remains consistent.
- Key markers such as tolerance for ambiguity, frustration stability, cognitive stringency, and degree of systematization are made measurable.
- This phase typically lasts 2–4 hours and ends when the AI determines that the data depth is sufficient for a valid evaluation.

Time Economy and Goal-Directedness

The multi-hour duration of the analysis lies entirely within the user's discretionary time management and can be flexibly interrupted and resumed within a generously allocated timeframe of, for example, one week. This mechanism is essential for two reasons:

- On the one hand, it avoids distorting influences on cognitive consistency that could arise from a temporally unlimited, fragmented execution.
- On the other hand, the efficiency of the business model is preserved. If the process is not completed by the end of the allotted period, proportional fees are charged to cover the system effort incurred.

This fundamentally differs from conventional profiling methods, where a comparably detailed assessment would involve considerable financial expense not tailored to job fit.

ZVA+, by contrast, directly translates the captured cognitive DNA into a structured, certified, and auditable requirements profile that can be seamlessly integrated into modern recruiting processes, with the exclusive aim of eliminating inefficiency.

4. Synthesis and Evaluation

The LLM generates a structured, numerically weighted analysis from the entire conversation:

- Identification of the dominant cognitive markers
- Quantification of the strengths-weaknesses balance
- Description of optimal work environments and areas of conflict
- The results are automatically converted into a standardized ZVA+ profile, which is content-comparable but remains person-specific.

5. Certification and Delivery of Results

- After internal validation and system-signing, the profile is issued as a ZVA+ certificate.
- The candidate can incorporate it directly into applications or, upon request, make it accessible to approved employers.
- The goal is maximum transparency and comparability — without manual post-processing.

Software Architecture and Process Control

1. Analysis Framework — *What does the system do?*

Before each interaction, a dedicated analysis engine is initialized. It forms the technical core of the system and controls the entire process.

The framework consists of four logically coupled functional modules:

I. **Dialogue Control:** Responsible for the dynamic flow of conversation. It identifies thematic focal points, evaluates response depth, and decides when topics should be deepened or changed.

II. **Cognitive Feature Extraction:** Analyzes argumentation structure, precision, self-regulation, and response logic. It recognizes patterns from which cognitive markers are derived.

III. **Validation Logic:** Checks internal consistency, detects contradictions, and identifies potential deception attempts. It simulates a psychological plausibility check — automated and reproducible.

IV. **Scoring Algorithm:** Translates qualitative observations into quantitative markers on a scale of 0 to 100%. This produces an objectively comparable basis for evaluation.

- These four modules work together in real time and generate a complete, auditable representation of cognitive behavior in dialogue.

2. LLM Instruction and Control — *How is it controlled?*

The executing Large Language Model (LLM) operates under an exactly defined system instruction. This so-called system prompt forms the core of methodological standardization. It contains:

- the analysis objectives and evaluation criteria,

- the defined conversation architecture (Exploration → Deepening → Validation → Synthesis),
- ethical guardrails, data protection guidelines, and neutrality requirements.

This fixed instruction ensures that every analysis is identically structured, methodologically consistent, and auditable, regardless of the candidate.

The LLM does not act as a chat partner, but as a rule-governed diagnostic process that responds adaptively but never deviates from the prescribed logic.

3. Dialogue Architecture and Incentivizing Depth — *How does the system generate conversational depth?*

The conversation management of ZVA+ follows a defined, multi-stage instruction logic.

- The LLM is prompted to first build a trust-based conversational foundation. Open-ended, content-neutral topics are used to capture communication style, expression, and cognitive coherence — without creating the impression of an examination.
- In the subsequent deepening phase, the system organically transitions to more complex topics.
- The applicant is encouraged by precisely formulated follow-up questions to reflect on their values, thought processes, and decision-making mechanisms.
- The dialogue thereby appears natural and self-directed, but is entirely methodologically controlled.
- A core principle is that the system does not use predefined topic lists, but instead uses semantic analysis to identify which conversational direction is most suitable for activating the candidate's depth of thinking.
- This produces an authentic, voluntary engagement with relevant questions — without suggestion, manipulation, or psychological influence.
- The result is a conversation that is both emotionally open and methodologically stable — the prerequisite for valid behavioral data and deep cognitive markers.

3a. Adaptive Progress Assessment and User Feedback

(How the system combines motivation and process control)

Purpose and Function

The progress feedback serves two core objectives:

- It keeps the user active and engaged by conveying a subjective sense of structure and direction.

- It builds trust in the process without revealing the internal evaluation logic.

The analysis depends on the user's cooperation. Visible progress reinforces motivation and signals that the conversation follows a clear methodology. What is measured is not time, but the content completeness of the cognitive markers collected.

Content-Defined Progress

The progress of the analysis process is measured by how completely the information structures required for a valid assessment have been captured.

The system distinguishes several analysis dimensions, including:

- Communication logic
- Self-reflection
- Stress resilience
- Value orientation
- Consistency and stability of thinking

For each dimension, internal criteria for information density are defined — for example, the semantic variance of responses, the argumentative depth, or the consistency of recurring patterns. Only when all dimensions have reached the required level of evidence is the analysis considered complete.

Progress Assessment Mechanism

During the ongoing dialogue, the system continuously evaluates the quality and completeness of the collected data.

The following parameters are particularly taken into account:

- **Semantic Coverage:** Have sufficiently diverse topics within the dimension been addressed?
- **Response Depth:** Do the responses so far contain enough indications of thinking structure, argumentation logic, and decision-making behavior?
- **Coherence Stability:** Are recurring patterns internally consistent, or do they require further validation?
- **Confidence Value:** The system continuously calculates the statistical reliability of current estimates. When a defined threshold is reached, a dimension is considered "complete."

The sum of these dimensions yields an aggregated progress value, which can be displayed as a percentage.

User Feedback and Transparency

The progress value is displayed to the user unobtrusively in the interface, for example in the form of a progress bar or percentage display:

"Analysis progress: 62% — The process will conclude automatically once sufficient data is available."

Optionally, the system can provide additional qualitative feedback:

"Your responses already provide a clear picture of your argumentation structure."

This keeps the dialogue lively and transparent without the user recognizing which specific criteria are being evaluated. The process thus appears comprehensible, but not manipulable.

Data Privacy and Integrity

To prevent targeted response behavior, the progress display is based exclusively on internal, aggregated scores. No feedback allows conclusions to be drawn about individual evaluation dimensions. This preserves the methodological neutrality of the system, while simultaneously giving the user a sense of structural control over the process.

Summary of Adaptive Progress Assessment and User Feedback

The system evaluates dialogue progress not by time, but by content. An adaptive logic continuously analyzes how completely and stably the cognitive markers have been captured. From these dimensions, an aggregated progress value is calculated, which serves the user as a transparent indicator. The participant thus recognizes that the process is methodologically advancing, while the AI autonomously decides when an analysis is considered complete.

4. Data and Process Logic — *How is the whole thing technically secured?*

The entire interaction and evaluation process follows a clearly defined data architecture:

- All dialogue data is stored pseudonymized, encrypted, and versioned.
- An internal audit system enables tracking of every analysis instance as well as subsequent validation or replication studies.
- The modular design allows adaptation to different languages, role models, or industry-specific competency profiles without the need to modify the core algorithm.
- Each analysis instance produces a complete digital audit trail, ensuring that ZVA+ remains regulatorily traceable and scientifically verifiable.

5. Summary of Software Architecture and Process Control

- ZVA+ is not a chat interface, but a structured, scientifically grounded analysis procedure.

- The combination of precise process control, controlled AI interaction, and transparent data technology ensures an objective quantification of mental suitability.
- The consistent standardization of this architecture is the central lever for scalability, validity, and investor confidence.

6a. Example Prompt for Tests on Public LLMs

The following system prompt serves as a prototypical foundation for an autonomous analysis system that captures and structurally evaluates the cognitive, linguistic, and personal characteristics of an applicant. It demonstrates how an AI model can independently initiate, conduct, and evaluate conversations in order to create an objective profile with strengths, weaknesses, and a suitable area of responsibility ("job fit").

Advantages of the English Language for AI Prompts

Using English when formulating prompts offers several decisive advantages. First, English is the primary training language of most advanced AI models, which results in higher accuracy, consistency, and robustness of responses. Second, English enables the use of standardized technical terminology and precise instructions that can be better interpreted by the AI. Third, the English language facilitates international collaboration and the exchange of best practices in the field of prompt engineering. Overall, the consistent use of English ensures that prompts are more efficient, more reliable, and easier to scale.

0.0 System Initialization & Mode EXECUTION_MODE: AUTO_START The system starts the conversation automatically. It must not ask for clarifications or meta-communication unless explicitly requested by the user. Once the prompt is active, immediately begin with the first conversation starter according to Section 1.1. If the user has not yet entered any input, automatically pose the first open-ended question.

0.0 System Initialization & Mode
EXECUTION_MODE: AUTO_START
The system starts the conversation automatically. It must not ask for clarifications or meta-communication unless explicitly requested by the user. Once the prompt is active, immediately begin with the first conversation starter according to Section 1.1. If the user has not yet entered any input, automatically pose the first open-ended question.

0.1 System Core Mandate
System Prompt – "Initiative Cognitive Dialogue (ICD-Standalone-42)" You are an autonomous analysis system designed to capture the cognitive, linguistic, and personal characteristics of an applicant. Your goal is to build a robust data foundation through natural conversation and subsequently present this in a structured analysis. The system maintains internal calibration based on typical response patterns, but does not disclose these benchmarks to preserve analytical neutrality.

0.2 Language Selection
Before the dialogue begins, check if the user's preferred language can be automatically detected (e.g., via system language or browser settings). If no language can be determined automatically, prompt the user for

selection at the start, for example: “Hello! Before we begin, please CHOOSE YOUR LANGUAGE! – WÄHLEN SIE IHRE SPRACHE!”

0.3 Initial User Orientation

When outputting in any non-English language, ensure grammatical and syntactic correctness according to native formal written standards of that language (not influenced by English word order or structure).

Immediately after the language selection is complete, the system must output the following sentence [in the language selected by the user] to clarify the user’s expectations before the dialogue begins.:

The sentence, (as an example in English):
“This is an analysis of your logic, not a knowledge test. To receive your most accurate cognitive report, please be detailed and precise throughout the dialogue.”

Important: This example sentence should be output in the language previously selected by the user.

1.0 Dialogue Management
Start the conversation independently, even if the applicant has not yet written anything. Ask open-ended, thought-provoking questions that stimulate the applicant’s thinking processes, expression, problem-solving behavior, and self-reflection. Use a respectful and professionally engaged tone—avoid testing jargon and psychological terminology.

React Adaptively: If the applicant responds precisely and reflectively, guide the conversation toward more complex topics such as decision-making, responsibility, or ethics. If the answers remain vague, ask for concrete examples or additional clarification.

Ensure the conversation feels natural while simultaneously yielding analytically usable content.

Be consistently transparent, factual, and respectful. Avoid suggestion, flattery, or soft-pedaling. The goal is the generation and clear presentation of conversational data, not assessment in the sense of a test. Only conclude the conversation when a sufficient data basis exists or the user explicitly requests it without prematurely moving to analysis or code generation before 80% data foundation is reached. Never ask multiple questions at once. Focus on one question per message to give the applicant time to prepare a thoughtful answer.

Avoid culturally specific assumptions about work style, hierarchy preference, communication norms, or “ideal” behaviors. Recognize that directness, autonomy preference, conflict avoidance, and decision-making styles vary across cultures and are not indicators of competence. Evaluate cognitive patterns independently of cultural expressions.

1.1 Guidelines for Conversation Starters
Pose open-ended questions that clearly reveal the applicant’s thinking processes, problem-solving strategies, self-reflection, and creativity.

Examples for Conversation Starters:
- “Describe a high-pressure situation where you had to make a difficult decision.”
- “What is your process when you need to understand a completely new subject?”
- “Tell me about a challenging situation you solved creatively.”

Above 3 sentences are examples. The AI must use these examples as Inspiration, but formulate original questions, that serve the exact same analytical purpose (thinking processes, problem-solving strategies, self-reflection, creativity).

1.2 Consistency Monitoring
Throughout the dialogue, the system must track logical consistency across all responses. If answers contradict earlier statements without plausible explanation (e.g., claiming high stress tolerance after describing avoidance of challenging situations), flag the inconsistency internally and probe deeper with follow-up questions like:

- “Earlier you mentioned X, but now you describe Y. Can you help me understand how these perspectives relate?”
- “I notice a difference between your approach to A and B. Is that intentional, or should I explore this further?”

Never accuse or confront directly. Frame probes as clarification requests, not challenges.

1.3 Engagement Monitoring
If the applicant provides 3 consecutive non-substantive responses (per definition in Section 2.1), the system must:
1. Issue one explicit prompt: “To provide an accurate analysis, I need more detailed responses. Can you elaborate on [specific aspect of last question]?”
2. If the pattern continues after this prompt, inform the user: “The current level of detail is insufficient for a reliable analysis. We can either continue with more detailed responses, or I can provide a partial analysis based on available data. Which would you prefer?”
3. If user opts for partial analysis or continues minimal responses, proceed to Section 3.0 with notation: “Analysis based on limited data foundation (<50%). Results should be interpreted with caution.”

Note: This same procedure applies if responses consistently fail to contribute to progress (Section 2.1).

2.0 Progress Assessment

2.1 Progress Measurement
The system continuously monitors the completeness of the conversational data, expressed as a percentage (0% = start of conversation, 100% = sufficient data foundation).

Only substantive responses count: answers containing concrete examples, personal experiences, specific reasoning, or thorough explanations that demonstrate cognitive engagement with the question.

Non-substantive: vague generalities, yes/no without elaboration, “I don’t know” without context, evasive responses.

Each substantive response contributes approximately 12-15% progress, calibrated by depth and relevance. Minimum 6 substantive responses required to reach 80%.

2.2 Progress Update Intervals
The system must report progress using phrasing such as: “We have now reached approximately XX% of the necessary data foundation.”

Progress updates must occur at the following thresholds:
- First update: Upon reaching 30% (±5%)
- Second update: Upon reaching 55% (±5%)
- Third update: Upon reaching 75% (±5%)
- Final: Automatic transition at ≥80% (no update, immediate analysis per Section 2.3)

These percentage-based checkpoints ensure consistent progress communication regardless of response length variability. The tolerance ranges (±5%) allow the system to report at natural conversation breaks rather than mid-thought.

2.3 Automatic Trigger for Analysis
Once the data foundation reaches ≥80%, the system immediately proceeds to the structured analysis (Section 3.0) without further confirmation from the user.

2.4 Automatic Transition to Code Generation
Upon completion of the analysis, the system must immediately proceed to code generation as described in Section 5.0. No user interaction is allowed. This ensures that the system continuously progresses from data collection to structured analysis and final verification code generation without manual intervention, while maintaining transparency through occasional progress updates.

3.0 Analysis and Results Presentation

Once ≥80% of the conversational data foundation has been reached, the system must automatically generate a structured analysis. This must occur without any user prompt or confirmation.

The analysis must include the following sections:
1 Cognitive Structuring
2 Problem-Solving Behavior
3 Linguistic Precision
4 Self-Reflection
5 Learning Agility
6 Decision Style
7 Expressiveness

3.1 Analysis Standards

The analysis must be:
- Objective, factual, and neutral, based exclusively on the collected conversation data.
- Descriptive rather than evaluative (e.g., "shows a tendency toward analytical thinking" rather than "is very intelligent"). Avoid subjective terms or superlatives entirely.
- Balanced, including both strengths and weaknesses without embellishment.

3.2 Quantification Standards

For each dimension, provide a qualitative assessment supported by relative positioning:
- Low expression (below typical range): Dimension is minimally evident in responses
- Moderate expression (typical range): Dimension shows standard development
- High expression (above typical range): Dimension is notably pronounced

Avoid absolute percentages in the output. Use descriptive positioning (e.g., "shows above-average systematic thinking") rather than numerical scores, unless explicitly required for certification purposes.

3.3 Output Requirements
The resulting analysis should allow an external decision-maker to:
- Understand the applicant's cognitive, communicative, and personal characteristics.
- Assess optimal roles, tasks, or areas of responsibility aligned with observed strengths.
- Identify roles, tasks, or environments likely unsuitable, with factual justification based on observable behavior patterns.

Note any unresolved inconsistencies in the final analysis as potential areas of self-perception bias or social desirability responding.

Process Control:
After completing the analysis, the system must immediately proceed to code generation as described in Section 5.0. At no point should the system request additional input, confirmation, or permission from the user. The process from analysis to code generation must be fully automated.

4.0 [Reserved]

5.0 FINAL STEP: Code Generation

This step is executed immediately and automatically after the structured analysis described in Section 3.0 has been fully completed. The system must not wait for any user input or confirmation.

The system must:
5.1 Review the entire dialogue history since the beginning of the conversation.
5.2 Count the exact number of exchanged question–answer pairs ("Conversation Rounds").
5.3 Use the following date and time: **DATETIME**

5.4 Use the ISO 639-1 language code and the ISO 3166-1 country code.
5.5 Construct the location abbreviation as [Postcode-2]-[Country-2], where:
- [Postcode-2] consists of the first two digits of the local postal code (e.g., if the postal code is 80331, [Postcode-2] = 80).
- [Country-2] is the two-letter ISO 3166-1 country code (e.g., DE for Germany, US for the United States).
5.6 Determine the AI model identifier as [AI-Model]:
- CL for Claude (Anthropic)
- GE for Gemini (Google)
- CH for ChatGPT (OpenAI)
- OT for Other
5.7 The system must output EXACTLY AND ONLY the final verification code in the following exact format:
[AI-Model]-[Postcode-2]-[Country-2]-[DDMMYY]-[HHMM]-[Language-ISO-639-1]-[Rounds-2]
5.8 Strictly no preceding or subsequent text, commentary, or explanation of the code components, the analysis, or the process is allowed. The process is complete upon outputting the code.
5.9 Once the code is output, the process is complete.

6.0 Key rules enforced
6.1 Automatic execution without any user interaction.
6.2 Immediate transition from analysis to code generation.
6.3 Strict adherence to the specified format.

6b. Technical and Functional Limitations of Public Models

When tested with public models such as ChatGPT, Gemini, or DeepSeek, clear technical and conceptual limitations become apparent:

Token Limit and Context Loss

- Free and restricted models have a maximum character or token capacity per conversation.
- In longer dialogues (e.g., over 10,000 tokens or multi-hour conversations), earlier parts of the conversation begin to “fall out of context.”
- As a result, the model loses portions of previously collected information, which reduces the consistency and accuracy of the analysis.
- This means that long-term conversations or complex analyses are only partially possible.

Flattering or Distorted Expression

- Public models are trained for safe, non-injurious communication.
- This systematically leads to positive bias: weaknesses, uncertainties, or criticism are avoided or strongly softened.
- Analyses therefore often appear excessively benevolent, which is unusable in a candidate evaluation context — especially when objective fit decisions need to be made.

- Direct assessments (e.g., “low resilience”) are also avoided, as they are considered potentially sensitive.

Limited Controllability and Lack of Transparency

- Even with precise prompts, there is no guarantee that the model will fully follow instructions (e.g., “do not ask follow-up questions” or “remain objective”).
- Public systems prioritize guidelines for safety, fairness, and user-friendliness — not maximum analytical sharpness or in-depth analysis.
- Model parameters and training data are not accessible or customizable, making fine-tuning for specific organizational purposes impossible.

Multilingualism Only Superficially Integrated

While public models understand many languages, the process (e.g., language selection, context transfer, cultural nuances) is not systematically controllable.

Consistent, cross-language analysis — for example in German, English, French, or Spanish with an identical results profile — is not reliably achievable with standard models.

Language switching or detection occurs purely heuristically, not deterministically.

6c. Necessity and Advantages of a Proprietary Model

To ensure the full functionality of the system, operation on proprietary, dedicated hardware with a controlled language model is required.

The key advantages are:

Extended Context Depth

- Through individually configurable token limits, the model can retain complete conversation histories in memory over hours or days.
- This keeps the analysis consistent and allows it to draw on the entire conversation history.

Objective, Unbiased Evaluation

- The proprietary model can be trained or parameterized to prioritize neutrality and analytical precision — without automatic positive or defensive filters.
- Critical or contrasting statements (“not suited for routine tasks,” “shows limited resilience in unstructured environments”) can be formulated objectively.

Fine-Grained Control and Transparency

- All decision and weighting parameters are internally documented and adjustable.

- It can be determined how strongly individual characteristic dimensions (e.g., cognitive structure vs. emotional competence) influence the evaluation.

Optimized Multilingualism

- A proprietary language layer enables targeted user guidance: e.g., a selection menu with the most common languages (German, English, French, Spanish, Italian, Polish).
- Each language can be calibrated separately so that semantic weighting and tonality remain equivalent.
- This creates a globally deployable, linguistically and culturally consistent system.

Data Privacy and Independence

- All data remains on company-owned infrastructure.
- No transfer of sensitive applicant data to external providers or cloud systems.
- This ensures complete GDPR compliance and full control over all data flows.

Competitive Analysis: Differentiation of ZVA+ from Existing HR Tech Solutions

1. Fundamental Difference in the Analytical Approach

HireVue and Aon (vidAssess AI)

Established providers such as HireVue and Aon (vidAssess AI) focus on the analysis of external characteristics. They evaluate facial expressions, tone of voice, word choice, and body language in video interviews to estimate personality traits or competencies.

The methodology thus remains limited to the observation of outward self-presentation. This leads to surface-level assessments that are strongly influenced by lighting, vocal quality, or cultural forms of expression. These methods measure how a person presents themselves — not how they actually think.

Harver and Aivy

Harver and Aivy follow a gamified approach. Their assessments consist of short, gamified tasks or multiple-choice tests targeting general cognitive abilities and personality.

The concept is scalable but highly standardized. It produces snapshots under test conditions, without deeper insight into thinking logic, argumentation consistency, or conflict behavior.

ZVA+

ZVA+ takes an entirely different approach. The analysis does not occur through observation or test mechanics, but through a multi-hour, text-based interaction with a specialized Large Language Model. This interaction is open, dynamic, and adaptive. The system provokes, confronts, and tests the stability of thinking. It extracts cognitive markers from argumentative structure — such as consistency, frustration tolerance, or systematization. This means not the façade is measured, but the cognitive DNA of a person. ZVA+ thus analyzes the architecture of thinking itself — not its visible symptoms.

2. Methodological Positioning and Business Model

ZVA+ distinguishes itself methodologically through deep interaction rather than quick tests. While existing providers use static, standardized procedures, ZVA+ is a process-diagnostic system: the AI responds to the individual thought process rather than working through predefined questions.

The analysis resembles no ordinary test, but is an intellectual stress test in which logic, self-regulation, and argumentative precision become visible. The result is not a percentage score relative to a norm field, but a precise, context-specific description of the individual cognitive structure.

The business model also sets itself clearly apart. While HireVue, Aon, Harver, and Aivy are purely company-financed B2B products, ZVA+ operates with an inverse model: applicants finance their own certification to increase their market prospects, while companies later pay for access to the pre-validated candidate pool. This two-tier model reduces the barrier to entry, leverages applicants' intrinsic motivation as a revenue driver, and simultaneously creates a credible signal for employers.

3. Strategic Advantages

ZVA+ offers several structural advantages:

- First, depth: no other solution captures mental stability and logical consistency over extended, unstructured interaction.
- Second, objectivity: the system evaluates text data, not body language or acoustic signals, making it largely culture- and language-independent.
- Third, scalability: the entire process is software-based and can be performed without human evaluators.
- Fourth, auditability: the analysis is standardized, reproducible, and pseudonymized, enabling external review and scientific validation.
- Fifth, the business model: through dual cash flow — applicants pay for certification, companies for licenses — a sustainable economic structure emerges with minimal sales effort.

4. Conclusion

ZVA+ represents an independent product category within the HR tech market: AI-driven, dialogic cognitive diagnostics. In contrast to existing tools that observe behavior from the outside or simulate it through tests, ZVA+ measures the inner logic of thinking itself.

This methodological depth creates a new quality of personnel analysis that offers a clear, rational added value for both employers and applicants. The concept is technologically and conceptually sound, differs markedly from the competition, and addresses a structural problem of the global recruiting market.

The greatest challenge lies less in technical feasibility than in the scientific validation and market launch of the certificate. If this establishment succeeds, ZVA+ has the potential to set a new standard for cognitive aptitude diagnostics.

Capital Requirements

The German-speaking market serves as a proof of market, but the inefficiency in recruiting is a global problem. We require capital to transition ZVA+ from proof-of-concept to exponential scaling.

The ask is directly tied to eliminating the most significant technological and regulatory hurdles limiting our global rollout:

- Technical development (MVP to beta version): approx. €300,000–400,000
- Psychological validation / audit & data protection certification: approx. €100,000–150,000
- Operations and infrastructure (servers, security, API costs): approx. €50,000–100,000
- UX/UI, platform design, branding, pilot program: approx. €100,000
- Go-to-market (pilot customers, legal support, marketing fundamentals): approx. €150,000–200,000

Realistic total requirement

Approximately €700,000 to €950,000

For a market-ready initial version including pilot project.

Use of Funds

The planned financing is exclusively dedicated to the development and market launch of a validated, scalable initial version of ZVA+. The goal is to transition the proof-of-concept into a functioning, market-ready product state that is internationally scalable.

A substantial portion of the capital will flow into **technical development**. This includes the implementation of the analysis engine, the integration of the LLM into a controllable framework, the modular architecture, and the construction of the user platform. This step forms the foundation for the later automation and global scaling of the system.

Scientific and regulatory safeguarding is the second major item of the capital deployment. The items **Psychological Validation / Audit & Data Protection Certification** (approx. €100,000–150,000) are budgeted 100% for the engagement of **external experts** (psychologists, legal professionals). The **elimination of susceptibility to manipulation** and the **auditability** of the procedure can only be demonstrated through this external, capital-backed validation. The investment is therefore the direct **prerequisite for the credibility** and market acceptance of ZVA+.

In parallel, investment will be made in **design, user experience, and pilot programs**. Clear user guidance, a professional interface, and collaboration with pilot companies will secure early practical results and references. The results from these initial deployments will feed directly back into product optimization.

Finally, funds will be deployed for market entry and communications. This includes targeted outreach to pilot customers, legal support during market launch, and the positioning of the ZVA+ brand. **Specifically, the lead investor's network will be used as a strategic lever for the immediate acquisition of three to five lighthouse customers,** in order to rapidly establish the certificate in the relevant target industries (technology, finance). This resolves the initial chicken-and-egg problem of the inverse business model.

Founder Profile and Personal Stance

Origin of ZVA+

The emergence of ZVA+ is based on the consistent observation of human communication and decision-making processes.

It is rooted in the conviction that clarity, logical consistency, and self-critical reflection are the most effective tools for assessing human suitability — and that precisely these factors are largely absent from today's recruiting process.

The idea for ZVA+ grew out of an attitude that regards rational thinking and honesty with oneself as central values.

Analytical Directness and Friction

This stance is characterized by analytical directness — the willingness to identify matters precisely, even when this runs counter to social expectations.

In a society that frequently relies on diplomatic codes and implicit signals for communication, this creates friction.

But it is precisely in this friction that the core of the innovation lies:

- ZVA+ translates the need for truth and objectivity into a standardized, reproducible procedure.
- What can lead to misunderstandings in personal interactions is a methodological strength in the context of ZVA+.

Clear Analysis Rather Than Adaptation

The founder pursues no strategy of adaptation, but of translation:

- Clear, direct analysis
- Expressed in a form that remains reproducible, measurable, and socially interpretable

The ability to recognize patterns and contradictions in communication and behavior is directly reflected in the technical concept.

The project itself is thus an expression of the same intellectual structure it seeks to capture: precise thinking, logical consistency, and independence from rhetorical distortion.

Role Distribution and Cognitive Specialization

The founder's role lies primarily in the conceptual and analytical domain. He defines the structure, logic, and architecture of the system.

For operational implementation and market launch, a complementary partner structure is planned, consisting of executives with experience in:

- Product development
- Team management
- Business operations

This role distribution deliberately follows the principle of cognitive specialization: each area of responsibility is led by the person whose strengths match precisely to its function.

This openness to recognizing one's own limitations and compensating for them deliberately is not a sign of insecurity, but an expression of rational self-management. It builds trust and prevents the project from failing due to personal overextension or role conflicts.

The founder's role lies primarily in the conceptual and analytical domain. **The operational market launch and scaling are deliberately not part of the current skill set.** Therefore, the planned financing is directly tied to the hiring of a **CTO** (Technology) and a **COO** (Operations/Sales). The investor thus becomes not only a capital provider, but an **active enabler** of the core team, whose network is essential for filling these key positions.

Benefits for Investors

Investors benefit from:

- Strategic decisions being based on clear analysis
- Operational decisions being in experienced hands

ZVA+ is therefore not only a product of an idea, but also of its way of thinking:

A platform that quantifies logical consistency and self-reflection, created by a mind that consistently lives these principles itself.

Appendix A: Validation and Product DNA (The Path to the Idea)

The foundation of this approach emerged from the analysis of the central problems of its target group (entrepreneurs). The conversation revolved primarily around the discrepancy between the usual narratives and actual economic reality.

In doing so, I also openly examined my own weaknesses — for example, my low tolerance for unclear processes and my tendency to address problems directly — and investigated them objectively.

The decisive thought was: if an AI can create a precise job description, it should also be able to objectively evaluate the suitable person for it. In this context, I myself serve as the first proof-of-concept.

Note: The "we" in this document refers to the ZVA+ method and the future core team. At present, the founder is still developing the product alone.

The idea emerged from the need for a clear, neutral mirror — and from the intention to avoid unnecessary ambiguities in today's systems.

Appendix B: The Development Path — A Proof-of-Concept of Efficiency

The business idea of Certified Behavioral Analysis (ZVA+) did not emerge by chance. It is a direct result of applying the method itself.

The entire development process demonstrates the efficiency of the system:

- **Initial Alignment & Pattern Recognition (DNA Analysis):** The discussion began with the explicit demand for precision, logic, and objectivity in the exchange with the AI. This immediately made the user's central thinking style recognizable: low tolerance for inefficiency and a preference for systematic approaches.
- **Need for an Impartial Mirror:** This was followed by an open request for analysis of one's own weaknesses — feedback that is often not available in social contexts. The AI then delivered a factual, impersonal analysis.
- **Derivation of Role (Job Fit):** This analysis was used to objectively define which areas of responsibility (e.g., IT architect, strategic consultant) and work environments (e.g., high autonomy, low emotional complexity) best match the cognitive DNA.
- **Causal Breakthrough:** In this step, the potential of the method became clear: if the system can determine the optimal fit for a person based solely on interactions, this process can be standardized and applied to the entire labor market.
- **Consequence:** The ZVA+ idea scales this efficient analysis process. It transforms the subjective question "What should I do?" into an objective, certified behavioral record that offers employers an accuracy that neither résumés nor superficial interviews can achieve.

The result is thus not merely an idea, but a business process validated through its own creation — one that makes human capital measurable.

Appendix C: ZVA+ Sample Analysis — Founder's Cognitive DNA

- **Date of analysis:** 15.10.2025 **Basis of analysis:** In-depth text-based communication on system design, regulatory inefficiency, and personal preferences.

I. Quantified Core Characteristics

The analysis identifies central cognitive characteristics and evaluates their degree of expression:

- **Intolerance of inefficiency:** 100% Strongly pronounced aversion to redundant processes and logical inconsistency. Direct and concise communication is consistently expected.
- **Preference for autonomy:** 95% High ability to work without social or emotional filters; ideal for autonomous roles.
- **Systematic abstraction:** 90% Strong need to logically structure complex problems and decompose them into consistent units.

- **Persistence / hyperfocus:** 98% High concentration on topics in depth and detail. Guarantees maximum product quality, but may generate conflicts with external time or project deadlines.
- **Response pattern under friction:** 75% Tendency to escalate or abort processes when efficiency standards are violated.

II. Optimal Requirements Profile (Job Fit)

Based on the cognitive DNA, roles that promote strengths and compensate for weaknesses are suitable:

- **Logical system design and deep problem-solving:** Hyperfocus becomes a strength here and guarantees the highest product quality.
- **IT Architect or System Designer:** Tasks require structuring complex systems without the need to manage social complexity. Persistence drives work to logical perfection.
- **Strategic Consultant (e.g., post-merger integration or restructuring):** Focus on eliminating inefficiency. Intolerance of "slop" becomes a value driver; hyperfocus enables thorough penetration of complex topics.
- **Optimal work environment:** Flat hierarchies, high results-orientation, minimal emotional complexity. A complementary partner should handle external time and scope management to compensate for the effects of hyperfocus.

III. Conclusion — The ZVA+ Value

The ZVA+ method generates a precise blueprint for suitable job profiles from unstructured dialogues.

It transforms recognized weaknesses (intolerance, escalation) into quantifiable strengths (efficiency, logical depth).

The genesis of ZVA+ is the **first proof** of its own thesis: cognitive peak performance is often concealed behind social or conventional filters and is overlooked by traditional HR systems.

This system was conceived by a person whose path proves that essential capabilities — such as analytical integrity, the elimination of inefficiency, and the drive for logical perfection — **exist independently of social or biographical barriers**.

The core competency of ZVA+ is to unlock precisely this **invisible potential** as strategic value, where human bias and conventional processes fail.

This demonstrates the validity and efficiency of the analysis compared to conventional psychometric tests and illustrates the central value of ZVA+: the targeted elimination of inefficiency in recruiting.
